In the second day of journey, we know how what happen when we press enter. The journey of code start we press enter so first the compiler translate the c sharp code into intermediate code Common Intermediate Code (CIL) or intermediate language (IL).an IL is low level programming language that service as an intermediate between high level programming language and native machine code. Then the IL is executed by the common language run time which is .net Framework runtime environment. The CLR performs just-in-time(JIT) compilation, that translate IL code into native machine code. Finally, the native machine code is executed by the computer processor.
